Russia's Norilsk smelter complex and a town in South Africa's eastern coal mining province have the highest sulfur dioxide (SO₂) emissions in the world, according to satellite data from U.S. space agency NASA.

The NASA-compiled data published on Monday was commissioned by environmental group Greenpeace India and used the space authority's satellites to track anthropogenic sulfur dioxide emission hot spots around the world.

Scientists say that excessive exposure to SO₂ particles causes long-term respiratory difficulties and stunted growth in infants among other problems.

Norilsk, 300 kilometers inside the Arctic Circle, has the largest individual SO₂ emissions, followed by the South African town of Kriel, about 150 kilometers east of Johannesburg,

Monday's report found.

The industrial city of Norilsk is home to Norilsk Nickel, the world's leading nickel and palladium producer.

The company is implementing a massive program to improve the ecology of the city and its surroundings.

The first stage of the program is complete. After the closure of an old nickel plant and reconstruction of nearby plants, emissions in the city's residential area fell by 30%, Nor Nickel said on Monday.

The second phase will involve a \$2.5 billion sulfur project to help to reduce sulfur dioxide emissions in and around Norilsk by 75% from 2015 levels by 2023.

Under snow for up to nine months of the year and in darkness for more than a month in winter, Norilsk has acquired a reputation as one of the most polluted settlements in the world because of its metals plants. Prisoners from Joseph Stalin's labor camps built the first smelters there 80 years ago.
