

How Is Climate Change Impacting Russia?

November 02, 2021

As world leaders gather in Glasgow for the COP26 climate summit in hopes of agreeing on a strategy to avoid catastrophic global warming, Russia stands to face significant changes from climate change in the coming decades.

Here's a look at some of the ways Russia, which is [warming](#) 2.5 times faster than the planet, is already being impacted by climate change — and how these processes will only intensify:

Melting permafrost

Roughly 65% of Russia's territory is [covered](#) in permafrost. As air temperatures have risen in recent decades, this soil that has been frozen for millennia has begun to thaw.

This melting is already reshaping the landscape of the tundra and is expected to cause significant damage to human settlements and key energy and transportation infrastructure. And as permafrost melts, it releases long-stored greenhouse gases like methane, triggering

an accelerating feedback loop of warming.

President Vladimir Putin recently [told](#) his government to come up with a plan to counter this threat, which is [projected](#) to cost the Russian economy billions of dollars by 2050.

Floods and droughts

Climate change will make catastrophic floods and heatwaves increasingly frequent in Russia, WWF scientist Alexei Kokorin [told](#) The Moscow Times this August. While overall precipitation might not increase, it will become more unpredictable, with prolonged periods of both heavy rain and drought becoming more likely.

This year, the republic of Sakha in northeastern Siberia saw a record drought that, when combined with higher-than-normal temperatures, exacerbated the historic wildfires that tore across the region.

Forest fires

While forests act as a natural carbon sink by absorbing excess greenhouse gases, they quickly become major greenhouse gas emitters if a forest fire hits — as trees they release CO₂ and harmful particles into the atmosphere when they burn.

Russia has seen increasingly severe wildfires in recent years, most of which have affected remote, hard-to-reach areas of Siberia and the Far East. This year, one Siberian wildfire [had a 2,000-kilometer frontline](#), making it impossible for firefighters to combat the blazes.

Russia's decarbonization strategy heavily [relies](#) on the country's forests to absorb excess carbon emissions, a plan some experts have met with [skepticism](#).

Desertification

As Earth's climate zones shift from the Equator to the poles, previously forested lands are turning into deserts.

The desertification process has already [caused](#) significant harm to communities in the Russian republic of Dagestan some 1,500 kilometers south of Moscow.

Russia's key agricultural regions are located near to Dagestan, and experts worry that desertification could spread to these regions and impact the country's food supply. If insufficient action is taken to combat climate change, desertification could reach Moscow itself by 2100, scientists at Aalto University [projected](#).
