

Russia's Record Floods Submerge Uranium Mines in Urals – Reports

April 22, 2024

Flooding in the Kurgan region. **Donat Sorokin / TASS**

Updated to add Rosatom's statement.

Russia's [worst](#) flooding in decades has submerged Soviet-era uranium mines in the Kurgan region, the investigative news outlet Agentstvo [reported](#) Monday, sparking fears that radioactive and chemical pollution could seep into the Tobol River.

State nuclear agency Rosatom, whose subsidiary operates the mines at the Dobrovolnoye uranium deposit, denied that its mining facilities were impacted by the flood.

Agentsvo reported that the Dobrovolnoye deposit is located within the flood zone in Kurgan's Zverinogolovsky district, citing a [map](#) published by local authorities on April 11, environmentalists and videos published by local residents.

The hundreds or even thousands of mine wells drilled into the deposit have compromised the natural protective barrier surrounding the uranium ore, Alexei Shvarts, the former head of

Alexei Navalny's Kurgan regional office who previously worked on uranium mining issues, told Agentsvo.

As a result, environmentalists [said](#) the latest flooding may have sent radioactive substances into the river, potentially affecting hundreds of thousands of people living near the banks of the Tobol downstream.

Local ecologists [said](#) that the mines have been accumulating "radioactive sludge" for years, while authorities have ignored numerous public protests against continued uranium mining in this area, which is prone to spring flooding from the Tobol River.

Rosatom [called](#) the reports that its facilities were affected by the floods "deliberate misinformation."

"Contrary to recent claims by anti-nuclear interest groups, the floods in the Kurgan region have not affected the Dalur JSC facilities. The mining site is strategically situated on elevated terrain, far removed from floodwaters, and has remained unaffected. Water levels in the Zverinogolovsky district are currently receding," Rosatom said in a statement emailed to The Moscow Times.

The agency said it was working alongside local authorities and Russia's emergencies ministry to monitor the flood situation.

"There is no evidence whatsoever of any contamination of water content," the statement said.

Andrei Ozharovsky, a nuclear physicist and antinuclear campaigner, told The Moscow Times that these mines, which were built in the 1980s, were previously flooded in 1994.

According to Ozharovsky, who surveyed the area several years ago, some wells that were not properly sealed now leak a radioactive solution of uranium salts, which has potentially made its way into the river.

Given that uranium is both radioactive and toxic, similar to other heavy metals, its presence in a river used for drinking purposes would pose a threat even in small concentrations.

"Of course, the Tobol is a huge river, and so this solution has been greatly diluted. But the concentrations are higher than usual," Ozharovsky said.

"This is undoubtedly dangerous because some people will drink this water, and uranium will enter their bodies. And internal radiation exposure is much more dangerous than external exposure," he said.

Rosatom has previously [dismissed](#) protests against uranium mining at Dobrovolskoye as "radiophobia combined with ignorance," claiming that the deposit is fully isolated from the Tobol River by natural barriers and ruling out potential leaks and river contamination.
